***Mark Scheme***

---

Mark schemes are prepared by the Principal Examiner and considered, together with the relevant questions, by a panel of subject teachers. This mark scheme includes any amendments made at the standardisation events which all examiners participate in and is the scheme which was used by them in this examination. The standardisation process ensures that the mark scheme covers the candidates' responses to questions and that every examiner understands and applies it in the same correct way. As preparation for standardisation each examiner analyses a number of candidates' scripts: alternative answers not already covered by the mark scheme are discussed and legislated for. If, after the standardisation process, examiners encounter unusual answers which have not been raised they are required to refer these to the Principal Examiner.

It must be stressed that a mark scheme is a working document, in many cases further developed and expanded on the basis of candidates' reactions to a particular paper. Assumptions about future mark schemes on the basis of one year's document should be avoided; whilst the guiding principles of assessment remain constant, details will change, depending on the content of a particular examination paper.

Further copies of this Mark Scheme are available from: [aqa.org.uk](http://aqa.org.uk)

It may contain some valid points which are not clearly linked to an argument structure:</p> <ul style="list-style-type: none"><li>-unstructured answer</li><li>-errors in the use of technical terms, spelling, punctuation and grammar or lack of fluency.</li></ul>                                                                                                                                                                                 |            |  |  |
| <p>An answer that would score full marks would be:</p> <p>An increase in blood sodium levels would be detected by the brain, which brings about a reduction in the release of the hormones aldosterone from the adrenal gland and angiotensin. Therefore less aldosterone travels to the kidney in the blood plasma. When the levels of aldosterone are reduced, the kidney tubules reabsorb less sodium into the body from the kidney filtrate. This results in more sodium being lost from the body via the urine, reducing the level remaining in the blood.</p> |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |            |  |  |

|  | <p>An answer that would score full marks would be:<br/>Children of this age are growing rapidly and therefore require a good source of protein in their diet. This can be obtained from lean meat, eggs, fish, milk or plant sources such as beans and lentils. The youngest children in this age group should drink whole milk but the oldest can change to half-fat or skimmed milk in order to reduce their intake of fat. Milk is also an important source of calcium which ensures the development of strong bones and teeth. Regular intake of oily fish will provide omega3 and omega6 fatty acids, as well as vitamin D. Vitamin D is required in order to incorporate calcium into bone. Children of this age also need iron found in red meat and dark-green leafy vegetables such as spinach to ensure that they produce enough red blood cells. They should obtain their energy mainly from complex carbohydrates with a low glycaemic index, rather than fat. Salt and sugar should only be added to food in very small amounts.</p> |  |  |
